Laplace Transform: $X(s) = \int_{-\infty}^{\infty} x(t)e^{-st} dt$

Use partial fraction expansion and the table to find the inverse Laplace transform.

$y(t) = x(t) * h(t) \rightarrow Y(s) = X(s)H(s)$

Transfer Function: $H(s) = \frac{Y(s)}{X(s)}$

$Y(j\omega) = X(j\omega)H(j\omega)$

You can find $H(j\omega)$ from $H(s)$ by replacing s with $j\omega$

If $x(t) = A \cos(\omega_0 t)$ then $y(t) = |H(j\omega_0)| A \cos(\omega_0 t + \angle H(j\omega_0))$

A delay system: $y(t) = x(t-T)$ $H(s) = e^{-sT}$ $H(j\omega) = e^{-j\omega T}$

Group delay = $d/d\omega [\angle H(j\omega)]$

A differentiator: $y(t) = dx(t)/dt$ $H(s) = s$ $H(j\omega) = j\omega$

An integrator: $y(t) = \int x(t)dt$ $H(s) = 1/s$ $H(j\omega) = 1/j\omega$

System is internally stable if all the poles are in the LHP

System is unstable if at least one pole is in the RHP or there are repeated poles in the imaginary axis

System is marginally stable if there is no poles in the RHP and there are some unrepeatd poles on the imaginary axis.

$|H(s)|_{s=p} = b_0 \frac{r_1 r_2 \cdots r_N}{d_1 d_2 \cdots d_N}$

$= b_0 \frac{\text{product of the distances of zeros to } p}{\text{product of the distances of poles to } p}$

$\angle H(s)|_{s=p} = (\phi_1 + \phi_2 + \cdots + \phi_N) - (\theta_1 + \theta_2 + \cdots + \theta_N)$
 $= \text{sum of zero angles to } p - \text{sum of pole angles to } p$

Form I Realization

$H(s) = \left(b_0 + \frac{b_1}{s} + \frac{b_2}{s^2} + \frac{b_3}{s^3} \right) \left(\frac{1}{1 + \frac{a_1}{s} + \frac{a_2}{s^2} + \frac{a_3}{s^3}} \right)$

Sampling Theorem: The minimum sampling rate (Nyquist rate) to avoid aliasing is twice or larger than the bandwidth of the signal (highest frequency in the signal).

Apparent frequency due to undersampling $f_a = |f - mf_s|$ $f_a < f_s/2$

The quantization level $L = 2^n$ where n is the number of bits per sample.

Quantization error $= \Delta x/2$ where $\Delta x = (x_{\max} - x_{\min})/L$

$$L = 2^n$$

$$\Delta x = \frac{x_{\max} - x_{\min}}{L}$$

Any quadratic equation can be reduced to the form

$$ax^2 + bx + c = 0$$

The solution of this equation is provided by

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

A general cubic equation

$$y^3 + py^2 + qy + r = 0$$

may be reduced to the depressed cubic form

$$x^3 + ax + b = 0$$

by substituting

$$y = x - \frac{p}{3}$$

This yields

$$a = \frac{1}{3}(3q - p^2) \quad b = \frac{1}{27}(2p^3 - 9pq + 27r)$$
